1. Using Image Generator, how do you label images?

1 / 1 point

- ☒ It's based on the directory the image is contained in
- ☐ TensorFlow figures it out from the contents
- ☐ It's based on the file name
- ☐ You have to manually do it

✓ **Correct**

That's right! The directory of the image is the label.

2. What method on the Image Generator is used to normalize the image?

1 / 1 point

- ☐ Rescale\_image
- ☐ normalize\_image
- ☐ normalize
- ☒ rescale

✓ **Correct**

You've got it! This is the correct method for normalizing images.

3. How did we specify the training size for the images?

1 / 1 point

- ☐ The target\_size parameter on the validation generator
- ☐ The training\_size parameter on the validation generator
- ☒ The target\_size parameter on the training generator
- ☐ The training\_size parameter on the training generator

✓ **Correct**

Exactly! target\_size specifies the image training size

4. When we specify the input\_shape to be (300, 300, 3), what does that mean?

1 / 1 point

- ☐ There will be 300 horses and 300 humans, loaded in batches of 3
- ☐ There will be 300 images, each size 300, loaded in batches of 3
- ☐ Every Image will be 300x300 pixels, and there should be 3 Convolutional Layers
- ☒ Every Image will be 300x300 pixels, with 3 bytes to define color

✓ **Correct**

Nailed it! input\_shape specifies image resolution.

5. If your training data is close to 1.000 accuracy, but your validation data isn't, what's the risk here?

1 / 1 point

- ☒ You're overfitting on your training data
- ☐ You're overfitting on your validation data
- ☐ No risk, that's a great result
- ☐ You're underfitting on your validation data

✓ **Correct**

Great job! The analysis corresponds too closely to the training data, and may therefore fail to fit additional data.

6. Convolutional Neural Networks are better for classifying images like horses and humans because:

1 / 1 point

- ☒ There's a wide variety of horses

**Correct**

Way to go! CNNs are better in this case as they are independent from prior knowledge and human intervention in feature extraction.

There's a wide variety of humans

**Correct**

You've got it! CNNs are better in this case as they are independent from prior knowledge and human intervention in feature extraction.

In these images, the features may be in different parts of the frame

**Correct**

Correct! The receptive fields of different neurons partially overlap such that they cover the entire visual field.

7. After reducing the size of the images, the training results were different. Why?

0 / 1 point

There was more condensed information in the images

The training was faster

There was less information in the images

We removed some convolutions to handle the smaller images

**Incorrect**

Not quite. Reducing the size doesn't condense information.
